

The Complete Money-Flow Screener Set for IDX

Assuming full data access: tick-level trades tagged by broker code, order-book depth, foreign/domestic classification, and clean EOD broker summary

The screeners aren't a flat list — they're a funnel where order matters. You gate first so you never compute expensive flow signals on garbage, then detect, then disprove, then confirm.

Stage 0 — Eligibility gate

Run first; cheap, brutal. Hard filters.

- **Liquidity screen:** median daily *value* traded over a rolling window, not volume — a stock can have huge volume at Rp50 and be untradeable. Reject anything you couldn't enter/exit in N days without being >X% of value.
- **State screen:** exclude suspended, pre-opening-only, ARA/ARB-pinned, and fresh IPOs (no flow history). These are where paper fills lie hardest.
- **Float screen:** low free float means small money moves price like big money — your flow signal is noise. Require minimum public float.
- **Data integrity screen:** broker summary complete for the full window; drop names with gaps so you don't mistake missing data for zero flow.

Stage 1 — Accumulation detection

The core “smart money buying” signals. Emit scores.

- **Broker concentration screen:** top-N net-buy brokers as a share of total net buy, or a Herfindahl/entropy measure. Concentrated = controlled accumulation; dispersed = retail noise.
- **Persistence screen:** the same small broker set net-buying across consecutive sessions (cumulative net lots over a rolling window), not a one-day blip.
- **Stealth divergence screen:** price flat or down while net accumulation rises — the classic quiet accumulation setup, and the highest-value signal in the whole set.
- **Foreign flow screen:** foreign net-buy persistence and magnitude relative to float; foreign brokers carry different signal weight than locals.
- **Accumulator VWAP screen:** estimated average price of the dominant accumulator vs current price — tells you whether they're in profit (may distribute) or underwater (may defend), setting risk posture.
- **Absorption screen (needs order book):** large sell pressure repeatedly absorbed without price dropping — accumulation hiding under apparent supply. Only visible with depth data.

Stage 2 — Distribution / trap detection

The layer that separates a real system from a naive follower. Most builders skip this.

- **Distribution screen:** brokers who were accumulating now net-selling into strength (price up + prior accumulator flipping). This is you becoming exit liquidity.
- **Markup-on-thin-volume screen:** price spiking on low value traded — a pump signature, not real demand.
- **Wash/churn screen:** the same broker showing high buy *and* high sell — manufactured volume to bait followers.
- **Rotation screen:** buying baton passing between related broker codes to disguise a single player — flag correlated broker behavior.

Stage 3 — Confirmation

Only on names surviving Stages 1–2. Emit scores.

- **Volume-confirmed breakout screen:** price breakout on rising value traded, confirming flow is translating to price.
- **Relative strength screen:** outperformance vs IHSG/LQ45/sector, so you're not just riding a market-wide tide.
- **Float-rotation screen:** accumulated lots as a fraction of free float and days-to-accumulate — high rotation means a player has taken meaningful control.

Stage 4 — Risk / portfolio exclusion

Post-signal, pre-order. Hard gates.

- **Event screen:** upcoming corporate actions, rights issues, earnings, suspension risk — flow signals get invalidated by events.
- **Crowding screen:** don't let several “same bandar” names dominate the paper portfolio; they're one correlated bet.
- **Gap/volatility screen:** cap exposure to names where overnight gaps make your next-open fill model unreliable.

Two structural notes. The Stage 2 layer is the one most builders skip and the one that makes broker-flow systems actually work — without it you're systematically buying late and holding distribution. And every screen should emit a *score*, not just a boolean, so Stages 1–3 compose into a ranked conviction signal rather than a binary filter; only Stages 0 and 4 are hard gates.
